How Block I/O Fits in a PLC System

Block I/O is a complete I/O interface that includes the functionality of the I/O rack, adapter, power supply, and I/O modules in a single unit. Connect sensors and actuators to the module and use the remote I/O cable to connect the block I/O to your programmable controller.

Connect the block I/O to your remote I/O link as you would any other device (Figure 1.2). The block looks like a 1/4 I/O rack to the processor, and uses two words of input image table memory and two words of output image table memory. The block is addressed directly on the remote I/O link.

Input and output data is scanned asynchronously and transferred back and forth between the block and the controller input and output image table.

Chapter Objectives

In this chapter, you will learn what is compatible with block I/O, how to determine what devices to use, and what fuse to use for outputs.

Input Compatibility

Block I/O inputs convert ac or dc signals from user devices to the appropriate logic level for use within the processor. Typical input devices include:

- proximity switches

AC block input modules are compatible with 1771 series output modules if the off-state leakage current of the module is less than the block module minimum off-state current and the on-state voltage minimum of the ac block input is greater than the supply voltage minus the on-state voltage drop across the 1771 output module. Some 1771 I/O modules that meet these specifications are:

When selecting devices to use with the block I/O inputs, verify that the on-state voltage and currents of the device fall into the on-state region for the block input. Also verify that the off-state current and voltage fall into the off-state region of the block I/O module (Figure 2.1).

Figure 2.1
dc Input Specifications

Figure 2.2
ac Input Specifications at 60Hz

Example: You want to use an ac 2-wire Bulletin 871C Proximity Switch for an input to a block I/O module. To determine if the switch is compatible with the block, verify the following:

$$I_{\text{block-off}} > I_{\text{leakage-switch}}$$

$$V_{\text{supply}} - V_{\text{switch-on}} > V_{\text{block-on}}$$

where:

$I_{\text{block-off}}$ = minimum off-state current of block input

$I_{\text{leakage-switch}}$ = maximum off-state leakage current of proximity switch

V_{supply} = minimum value of supply voltage

$V_{\text{switch-on}}$ = maximum on-state voltage drop of proximity switch

$V_{\text{block-on}}$ = minimum on-state voltage specification

Simplified schematics of ac and dc input circuits are shown in Figure 2.3 and Figure 2.4.

Output Compatibility

The block I/O may be used to drive a variety of output devices. Typical output devices compatible with the block I/O outputs include:

- motor starters
- solenoids
- indicators

When designing a system, ensure that the block I/O output can supply the necessary surge and continuous current for proper operation. Take care to ensure that the surge and continuous current are not exceeded. Damage to the module could result.

The block I/O outputs are capable of directly driving the block I/O inputs of the same type.

AC Outputs

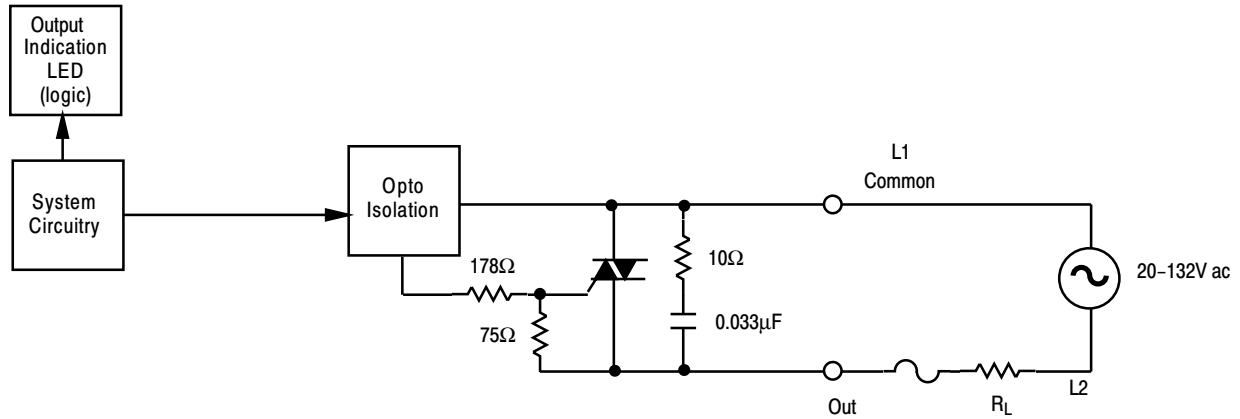

The ac output circuits for block I/O are capable of driving ac loads with a maximum surge current (inrush) of 10A/1200 Watts and a maximum holding current of 300mA/36 Watts at 60°C (600mA/72 Watts at 30°C). The maximum drive characteristics are shown below.

Figure 2.5
ac Output Drive Current

The drive circuit for ac outputs is shown in Figure 2.6.

Figure 2.6
Simplified Schematic of ac Output Circuit

When sizing output loads, check the documentation supplied with the output device for the surge and continuous current needed to operate the device. Refer to Table 2.A to determine which Allen-Bradley products will directly interface to the outputs.

Example: The output device is an ac solenoid operated air valve with an inrush current (surge) of 1.995A for 10ms and a holding current (continuous) of 275mA. Figure 2.7 shows that the load of the output device is within the operating specifications of the ac output.

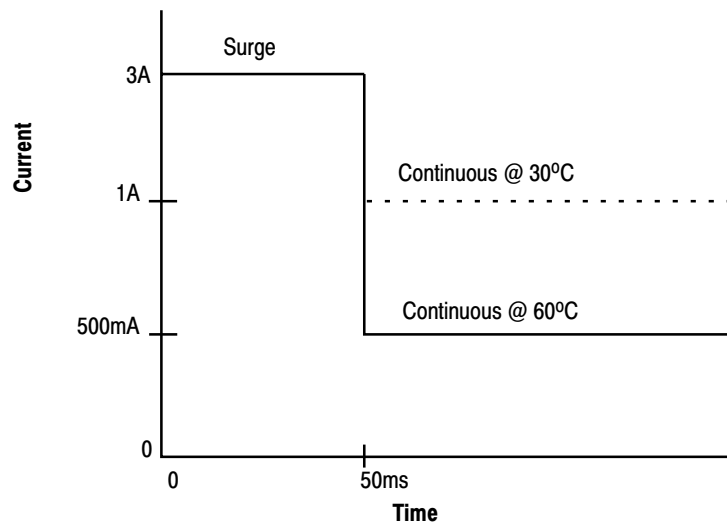

Figure 2.7
ac Output Drive Current Load for ac Air Valve

DC Outputs

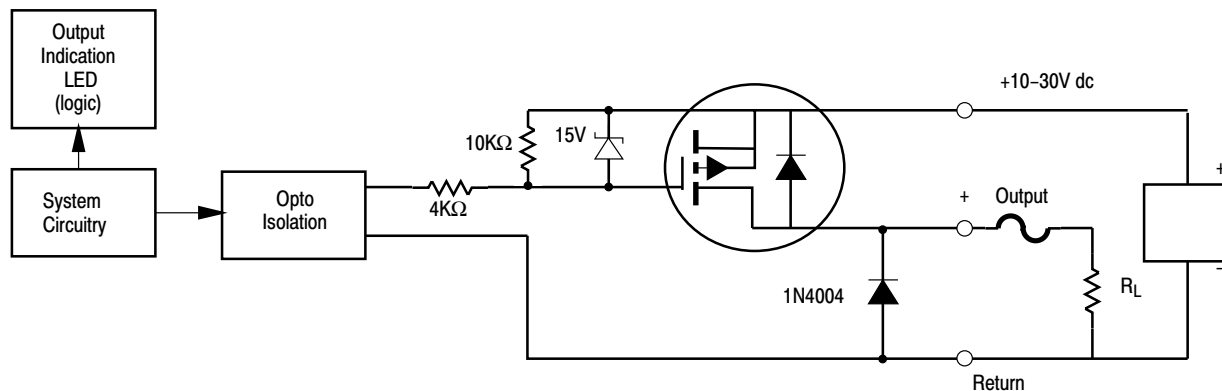

The dc output circuits for block I/O are capable of driving dc loads with a maximum surge current (inrush) of 3A/72 Watts and a maximum holding current of 500mA/12 Watts at 60°C (1A/24 Watts at 30°C). The maximum drive characteristics are shown below (Figure 2.8).

Figure 2.8
dc Output Drive Current

The drive circuit for dc outputs is shown in Figure 2.9.

Figure 2.9
Simplified Schematic of dc Output Circuit

12247-I

When sizing output loads, check the documentation supplied with the output device for the surge and continuous current needed to operate the device. Refer to Table 2.A to determine which Allen-Bradley products will directly interface to the outputs.

Relay Output

The relay outputs on block I/O modules are electro-mechanical outputs and do not require specific compatibility with the load device as to current sinking or sourcing.

Figure 2.10
Simplified Schematic of Relay Output Circuit

Fusing

The 16- and 32-point ac and dc block I/O modules are internally fused to protect the module. No external power fusing is required. Outputs are not fused. Fusing of outputs is recommended. If desired to fuse an output, you must provide external fusing.

Table 2.B
Recommended Fuses

Type of Circuit	Part Number ¹	Size	Rating in Amps	Maximum Surge Current ² (repeatable every 2s)
ac	SAN-O SS2-1.0	0.25 in. x 1.25 in.	1.0A	3.0A for 50ms

	SAN-O MQ4-800	5mm x 20mm	800mA ³	2.0A for 50ms

¹ **Note:** Do not substitute another fuse for those listed.

² The recommended fuses will withstand surges of the above listed currents for the time specified.

³ Current must be limited to 650mA when using this fuse.

Both ac and dc block I/O modules (except relay output modules) are derated linearly above 30°C up to and including 60°C, as shown in Table 2.C.

For modules with relay outputs, refer to Appendix A for output current and surge current ratings.

¹ PLC-5/15 series A and PLC-5/15 series B prior to revision H (B/H) can only address 3 blocks.

² PLC-5/25 revisions prior to A/D can only address 7 blocks.

Installing the Block I/O

Figure 3.1 shows the mounting dimensions for the block I/O module. Mount the blocks vertically with a minimum of 2" between blocks. This air gap is necessary to maintain proper cooling air flow through the block.

Mounting on a DIN Rail

Connecting Wiring

Make wiring connections to the removable terminal block which plugs into the front of the block.

ATTENTION: The terminal blocks are not keyed to prevent incorrect insertion. If you remove a terminal block, make certain that each terminal block is inserted with the lower row of screws on the outside of the block (positioned toward the outside of the module).

Termination Resistor

A termination resistor must be installed on the last block in a series. Connect the resistor as shown in Figure 3.23.

Figure 3.23
Installing the Termination Resistor

Surge Suppression

Output modules contain surge suppression circuitry for the block output devices. The ac output modules provide an RC network to limit the magnitude of voltage transients that may occur when a device is wired in parallel or series with hard contacts. The dc output modules have clamping diodes that shunt voltage transients to the power supply.

Important: We recommend that you use an additional suppression device if an output module is being used to control an inductive device such as:

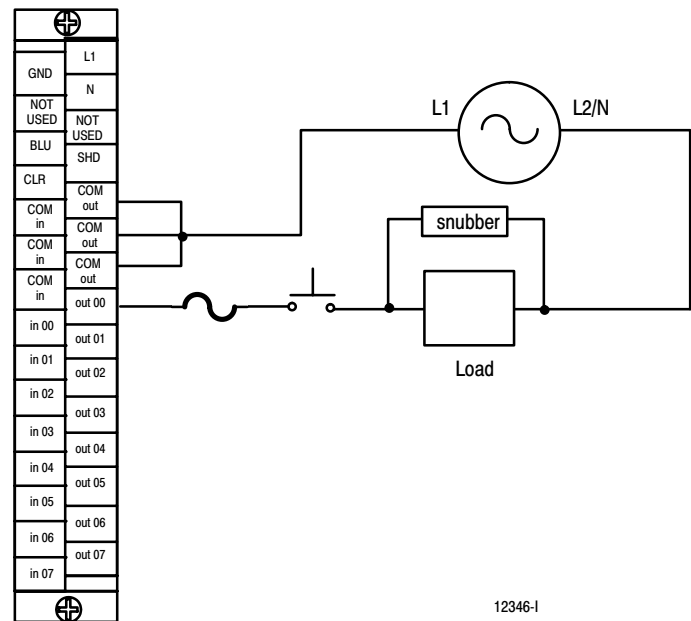

- relays ▪ motor starters
- solenoids ▪ motors

and is in series with or parallel to a “hard contact” such as:

- pushbuttons ▪ selector switches

By adding a suppression device directly across the coil of an inductive device, you will prolong the life of the output devices and switch contacts. Figure 3.24 shows an output module with a suppression device.

Figure 3.24
Connecting Surge Suppression Devices

The impedance characteristic is the most important factor in selecting a suppression device; thus no single suppression device can be recommended for every possible load. Table 3.C shows acceptable Allen-Bradley suppression devices and their catalog numbers for typical loads.

Table 3.C
Allen-Bradley Suppression Devices

Suppression Device	Catalog Number
Motor Starter Bulletin 509	599-K04 ¹
Relay Bulletin 700 Type N or P	700-N24 ¹
Miscellaneous	700-N24 ²

¹ Maximum coil voltage 150V ac or dc

² Bulletin 700-N24 is a universal surge suppressor. You can use it on electromagnetic devices with the limitation of 35 sealed VA, 150V.

Remote I/O Link Wiring

Blocks must be wired in series as shown in Figure 3.25 or Figure 3.26. Do not attempt to wire any block in parallel.

The number of blocks used depends not only on the user requirements but also on the system used. Refer to Table 3.A (page 3-1) for maximum block usage for individual systems.

Figure 3.25

Figure 3.26
Series Configurations for Block I/O Using the SLC Programmable Controller

Extended Node Capability

If this is the last remote I/O adapter on the remote I/O link in a PLC system, you must use a terminating resistor to terminate both ends of the remote I/O link (scanner end and last block end). The size of the terminator is determined by the system configuration.

Older system configurations must use a 150 ohm resistor at both ends. With newer devices that can support it, you can use an 82 ohm termination resistor at both ends. The 82 ohm terminators provide “extended node” capability which allows you to have up to 32 physical devices on the remote I/O link. (The number of logical racks capable of being addressed by the scanner is not affected.)

ATTENTION: Devices that are operating at 230.4K baud must have 82 ohm terminators in place for proper operation.

Compatibility of 1771 I/O Products with Extended Node Numbers

Certain products are **not compatible** with extended node capabilities obtained with the use of 82 ohm terminators. Table 3.D lists those products that are **not compatible**.

Selecting Remote I/O Link Speed

The remote I/O link can operate at three speeds: 57.6K, 115.2K or 230.4K bits/s. The selection of link speed is dependent on the scanner/processor used, throughput requirements, distance required and the type of remote I/O devices being used.

Throughput Requirements

The throughput, a portion of which is I/O scan time, must be balanced against the distance requirements for the application. The typical discrete I/O scan time is shown in Table 3.E below. Use these values along with your processor/scanner manual to determine system throughput.

Table 3.E
I/O Scan Time vs. Remote I/O Link Distance

	57.6K Bits/s	115.2K Bits/s	230.4K Bits/s
Typical Discrete I/O Scan Time (each block)	10ms	7.0ms	3ms
Remote I/O link distance	10,000 ft.	5,000 ft.	2,500 ft.

Configuring Your Block I/O for PLC Family Programmable Controllers

Chapter Objectives

In this chapter, you will learn how to configure your block I/O when used with PLC family programmable controllers. This includes the following:

- setting the configuration switches
- addressing the block I/O

Setting the Configuration Switches

Each block I/O module has two 8-position switches for setting:

- starting I/O group
- I/O rack number
- communication rate
- last chassis
- last state
- complementary I/O
- input filter speed (dc inputs only)
- processor restart/lockout

These switches are accessible by opening the clear plastic door on the front of the module (Figure 4.1).

ATTENTION: Cycle power to the block I/O module after setting the switches.

- PLC-5/11 can scan rack 03
- PLC-5/20, PLC-5/30, PLC-5/40, PLC-5/60 can scan racks 01–07

The SLC 500 controllers communicate with the block I/O using an I/O Scanner module (cat. no. 1747-SN series A). Refer to the user manual for the 1747-SN/A Scanner module for more information.

Note: These block I/O modules are **not** compatible with the **1747-DSN** Distributed I/O Scanner module.

Each block I/O module uses 2 words of output image table memory and 2 words of input image table memory. Each block occupies 1/4 rack of data table, with 4 blocks comprising 1 logical rack. Image table usage for one assigned rack number and examples of image table usage are shown in Figures 4.2 through 4.10.

Using Complementary I/O

PLC-2 and PLC-5 family processors support a complementary I/O configuration. Complementary I/O can allow you to maximize memory usage without increasing memory size. Refer to the user's manual for your processor to see if it supports this type of configuration.

You configure complementary I/O by duplicating an I/O rack number of one I/O chassis (primary) in another I/O chassis (complementary), I/O group for I/O group. The I/O modules in the complementary chassis perform the opposite function of the corresponding modules in the primary chassis.

Important: Series A block I/O modules do not support complementary I/O. If using complementary I/O, use series B modules.

When using I/O racks in a complementary configuration, the block I/O must be paired with a device which occupies 1/4 rack of I/O space (i.e. primary and complementary must be the same logical rack size).

Note: The 1747-SN series A is not capable of supporting complementary I/O.

Figure 4.11
Processor Data Table Use with Complementary I/O

Remote rack numbers which can have a complementary rack are rack numbers 01 thru 07 only (Table 4.H).

When configured as complementary I/O:

- PLC-2 can scan racks 01–07
- PLC-5/11 can scan rack 03
- PLC-5/20, PLC-5/30, PLC-5/40, PLC-5/60 can scan racks 01–07

Troubleshooting

Chapter Objectives

In this chapter you will learn about the indicators on the block I/O module, and how to use them to troubleshoot the unit.

Indicators

Each block I/O module has indicators (Figure 5.1) which provide indication of module status. Each module has the following:

Indicator	Color	Quantity	Description
COMM	Green	1	Indicates whether communication is occurring between processor or scanner and the block module
STATUS	Red	1	Indicates hardware or software error, and if communication has failed
I/O Status	Red	16	Reflect the state of the individual inputs and/or outputs (on or off)

Figure 5.1 shows the location of the indicators. Refer to Table 5.A for status indications reported by the indicators.

Figure 5.1
Indicators on the Block I/O Module

Table 5.A
Troubleshooting Chart

Indication	Probable Cause	Corrective Action
Green COMM indicator on Red STATUS indicator off I/O status indicator on/off	Normal operation	None required
Red STATUS indicator on	Block failed self-test, or a major fault is detected.	Cycle power to the block. If problem persists, replace the block.
Red STATUS indicator flashing Green COMM indicator off	Communication failure – RIO cable off, 100ms between valid frames, 20ms idle time exceeded. Improper processor or scanner switch settings.	Check remote I/O cable connections, verify scanner or processor switch settings.
Green COMM indicator off	No communication with processor, scanner etc.	Check that power is applied to block. Make sure that proper number of blocks are configured. Check remote I/O link for duplicate address.
Green COMM indicator flashing	Reset command (or output disable bit for SLC) has been issued by processor or scanner.	Check program. Correct as necessary. Check terminator, resistors and cable wiring.
	SLC or programmable controller in program mode.	Place in run mode.
COMM and STATUS indicators alternately flashing	Processor restart lockout is selected and a fault has occurred. (Communication to block is established.)	Cycle power to block.
